

Embedding Space Interpretability: Mortality vs Readmission

Figure 1. Embedding Space Interpretability across Clinical Tasks. (A, D) Linear probe R² across clinically curated variables. Variables encompass validated error archetypes, intervention proxies, and reference physiological domains. In both tasks, hemodynamic intervention counters (e.g., CVP Count) and demographic variables are strongly encoded, while raw physiological values like Albumin remain poorly encoded by the embedding space. (B, C, E, F) SHAP feature importance for the Numerical vs Semantic models. Semantic model dimensions are annotated with their top three unique clinical correlates (by univariate explained variance). The semantic model relies heavily on gender dimensions (mortality) and hepatic markers (readmission), aligning with the discovered error archetypes.
